Joints are locations in the body where bones meet. They enable movement and are classified by either their structure or function. Structural classifications of joints include fibrous, cartilaginous, and synovial joints. Functional classifications of joints include immovable, slightly movable, and freely movable joints.

The 3 Types of Joints in the Body - ThoughtCo

A joint, also known as an articulation or articular surface, is a connection that occurs between bones in the skeletal system. Joints provide the means for movement. The type and characteristics of a given joint determines its degree and type of movement. Joints can be classified based on structure and function.

The point at which two or more bones meet is called a joint or articulation. Joints are responsible for movement (e.g., the movement of limbs) and stability (e.g., the stability found in the bones of the skull). There are two ways to classify joints: on the basis of their structure or on the basis of their function.

What is clear is that no single mechanism is responsible and different modes of lubrication work at different stages of joint function. The joint is lined by wear resistant hyaline cartilage and is bathed by synovial fluid. Unlike a typical newtonian fluid synovial fluid has a viscosity that decreases with increasing shear rate.
