Understanding the Disorder Paradoxical Vocal Fold Motion Disorder (PVFMD) PVFMD is a breathing disorder that is caused by the abnormal movement of the vocal folds during breathing. The vocal folds are located on top of the airway and typically open wide for breathing to allow air to pass through, and the vocal folds close together for talking in order to allow the vocal folds

Immunohistochemical analysis. Ten-micrometer cryostat coronal sections of vocal folds were prepared and air dried. Double immunohistochemical staining was performed to detect HA and collagen type III in normal and scarred vocal folds, with nuclear counterstaining by TOTO-3 (Molecular probes, Eugene, OR).

The vocal ligament is the tension-bearing element in the vocal folds at high pitches. It has traditionally been treated as a vibrating string, with only length and longitudinal stress governing its normal mode frequencies. Results of this investigation ...

### Normal vibration frequencies of the vocal ligament

Reason for the breathing problems: Normal laryngeal nerves and muscles move the vocal folds to the closed position during crying, sound production (newborn), or speech/singing (older children and adults), and move the vocal folds apart during breathing. Two-sided vocal fold paralysis makes this impossible. The vocal folds stay close together during inhalation, causing a high-pitched, squeaky noise. Diagnosis: Two-sided paralysis may look similar to laryngomalacia.

Early vocal fold cancer also appear as whitish or reddish lesions, but have abnormal-looking cells that have invaded the boundary of the top layer of the vocal fold. Early cancer may affect one or both vocal folds and are often referred to as T1 or T2 type vocal fold cancers that have not spread to neck lymph nodes or elsewhere in the body.

The "true vocal cords" are distinguished from the "false vocal folds", known as vestibular folds or ventricular folds, which sit slightly superior to the more delicate true folds. These have a minimal role in normal phonation , but can produce deep sonorous tones, screams and growls.

### Vocal cords - Wikipedia

The vocal folds are to separate structures which are located in the larynx or voice box. Humans have two vocal folds which open and close during normal breathing, and during sound production, or phonation, the vocal folds come together and vibrate. The vocal folds are intricately layered, which is the reason for unique sound production.

Voice is produced by vibration of the vocal folds. The vocal folds are a pair of pliable shelves of tissue that stretch across the top of the trachea (windpipe). They are enclosed within the thyroid cartilage, which is the hard structure that forms the mass in the neck known as the Adam's apple. The vocal folds, together with the muscles and cartilages that support them, are
